Summer School on Effective HPC for Climate and Weather

Input/Output and Middleware

Luciana Pedro, Julian Kunkel
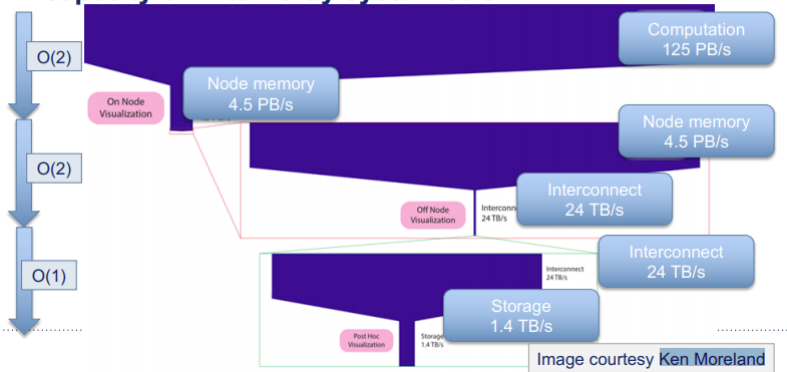

Department of Computer Science, University of Reading

18 June 2020

Outline

Five orders of magnitude between compute and I/O capacity on Titan Cray system at ORNL

Image courtesy Ken Moreland

The problem is not going away

How does Summit compare to Titan

Feature	Summit	Titan
Application Performance	5-10x Titan	Baseline
Number of Nodes	~3,400	18,688
Node performance	> 40 TF	1.4 TF
Memory per Node	>512 GB (HBM + DDR4)	38GB (GDDR5+DDR3)
NVRAM per Node	800 GB	0
Node Interconnect	NVLink (5-12x PCIe 3)	PCIe 2
System Interconnect (node injection bandwidth)	Dual Rail EDR-IB (23 GB/s)	Gemini (6.4 GB/s)
Interconnect Topology	Non-blocking Fat Tree	3D Torus
Processors	IBM POWER9™ NVIDIA Volta™	AMD Opteron™ NVIDIA Kepler™
File System	120 PB, 1 TB/s, GPFS™	32 PB, 1 TB/s, Lustre®
Peak power consumption	10 MW	9 MW

Data courtesy A. Geist (ORNL)

OAK RIDGE

I/O Bottleneck

Kunkel et al. [105] analyze historical data from the German Climate Computing Center (DKRZ) and predict processor performance growth by 20x each generation ($\sim$5 years), while storage throughput/capacity improves by just 6x.

Exascale Storage Systems – An Analytical Study of Expenses

	2004	2009	2015	2020	2025	Exascale (2020)
Performance	1.5 TF/s	150 TF/s	3 PF/s	60 PF/s	1.2 EF/s	1 EF/s
Nodes	24	264	2500	12,500	31,250	100k-1M
Node performance	62.5 GF/s	0.6 TF/s	1.2 TF/s	4.8 TF/s	38.4 TF/s	1-15 TF/s
System memory	1.5 TB	20 TB	170 TB	1.5 PB	12.8 PB	3.6-300 PB
Storage capacity	100 TB	5.6 PB	45 PB	270 PB	1.6 EB	0.15-18 EB
Storage throughput	5 GB/s	30 GB/s	400 GB/s	2.5 TB/s	15 TB/s	20-300 TB/s
Disk drives	4000	7200	8500	10000	12000	100k-1000k
Archive capacity	6 PB	53 PB	335 PB	1.3 EB	5.4 EB	7.2-600 EB
Archive throughput	1 GB/s	9.6 GB/s	21 GB/s	57 GB/s	128 GB/s	-
Power consumption	250 kW	1.6 MW	1.4 MW	1.4 MW	1.4 MW	20-70 MW
Investment	26 M€	30 M€	30 M€	30 M€	30 M€	$200 M[4]

Table 1. DKRZ System characteristics; future systems are a potential scenario

Capacity vs Bandwidth

■ Areal density increases by 40% per year
  – Per drive capacity increases by 50% to 100% per year
  – 2008: **500 GB**
  – 2009: **1 TB**
  – 2010: **2 TB**
  – 2011: **3 TB**   8x
  – 2012: **4 TB**

  Takes longer and longer
  to completely read each
  new generation of drive

  – 2014: **6 TB**
  – 2015: **8 TB**
  – 2016, 2017: **10 TB**
■ Drive interface speed increases by 15-20% per year
  – 2008: 500 GB disk (WD RE2): **98 MB/sec**
  – 2009: 1 TB disk (WD RE3):   **113 MB/sec** (+15%)
  – 2010: 2 TB disk (WD RE4):   **138 MB/sec** (+22%)   1.5x
  – 2013: 4 TB disk (WD SAS):   **150 MB/sec** (+ 8%)

Input/Output

Input/Output (I/O) is simply data migration.

- Memory ⇔ Disk

I/O is a very expensive operation.

- Interactions with data in memory and on disk.

How is I/O performed?

- I/O Pattern
  - ▶ Number of processes and files.
  - ▶ Characteristics of file access.

Where is I/O performed?

- Characteristics of the computational system.
- Characteristics of the file system.

I/O Performance

- There is no "One Size Fits All" solution to the I/O problem.

- Many I/O patterns work well for some range of parameters.

- Bottlenecks in performance can occur in many locations.
  - Application and/or file system.

- Going to extremes with an I/O pattern will typically lead to problems.

- Increase performance by decreasing number of I/O operations (latency) and increasing size (bandwidth).
I/O Types

**Serial, multi-file parallel and shared file parallel I/O**

**Serial I/O**
Parallel Multi-file I/O

**Parallel Shared-file I/O**

Access Patterns

What are the problems?

Not enough I/O capacity on current HPC systems, and the trend is getting worse.

If there's not enough I/O, you can't write data to storage, so you can't analyze it: lost science.

Energy consumption: it costs a lot of power to write data to disk.

Opportunity for doing better science (analysis) when have access to full spatiotemporal resolution data.

Data Storage
- As we are moving towards exascale, the gap between computing power and I/O bandwidth will widen and researchers are looking for solutions to tackle this problem.

- There are essentially three lines of research:
  - at hardware level,
  - at middleware level,
  - and at application level.

Hardware Level

- Non-volatile memory (NVM)
  - Non-volatile memory (NVM) is a type of computer memory that can retrieve stored information even after having been power cycled.
  - The capabilities of NVM (i.e., capacity, bandwidth, energy consumption) are somewhere in-between main memory and persistent storage, thus it is often used as a "caching" solution between these two layers.
- Burst buffer (BB)
  - Burst buffer (BB) is a fast and intermediate storage layer positioned between the front-end computing processes and the back-end storage systems.
  - HPC applications often show bursty I/O behavior (i.e., all processes read/write at the same time) and burst buffers help to absorb these workloads.
- Multi-layer Storage Hierarchy (Examples)
  - Attached SSDs to compute nodes to aggregate many small I/O requests into few larger ones and/or to compute nodes to speed-up MPI-IO.
  - Multi-layer storage hierarchy with NVM, SSDs, and different types of hard disks.

Middleware Level

- Solutions in I/O middleware.
  - E.g., file systems, I/O interfaces.

- Software framework that overlaps computation and I/O operations by dedicating a single core to I/O tasks.

- I/O abstraction framework for HPC applications that enables switching between different I/O transport methods with little modification to application code.

- File systems that improves the scalability of file systems by letting compute nodes manage metadata instead of a centralized server.

Application Level

- **In-situ analysis**

    - In biology and biomedical engineering, in situ means to examine the phenomenon exactly in place where it occurs (i.e., without moving it to some special medium).

    - Rather than applications writing their raw output to storage to later be read again for post-processing (e.g., visualization, filtering, statistics), in-situ processing removes this overhead by performing the analysis directly on the same machines as where the applications run.

    - ParaView [67], Dax [130], and Damaris/Viz [59] are tools for large-scale in-situ visualization.

Discussion

- Mismatch between the massive computational performance of processors and relatively limited I/O bandwidth of storage systems.
- Three methods to alleviate this problem: new hardware technology, new I/O middleware, and application-specific solutions).
- Hardware technology shows promising solutions, but different systems might employ different solutions, reducing the portability and increasing the complexity.
- Middleware can alleviate some of this complexity with solutions such as ADIOS.
- In-situ analysis is an example of how application-specific solutions can be used to improve I/O throughput and thus application performance.
- No one-size-fits-all solution to the storage problem and programmers must take I/O into careful consideration when developing applications.

Middleware

- Middleware is software occupying a middle position between application programs and operating systems.
- Common middleware examples include database middleware, application server middleware, message-oriented middleware, web middleware, and transaction-processing monitors.

Operating Systems and Middleware

- Operating systems and middleware are software used to support other software, such as the application programs you run. But operating systems and middleware are not the same!

  - An operating system provides the services in its Application Programmer Interface (API) by making use of the features supported by the hardware.

    - It might provide API services of reading and writing named, variable-length files by making use of a disk drive's ability to read and write numbered, fixed-length blocks of data

  - Middleware provides the services in its API by making use of the features supported by an underlying operating system.

    - It might provide API services for updating relational database tables by making use of an operating system's ability to read and write files that contain the database

Middleware

- Middleware is in the middle of the vertical stack, between the application programs and the operating system.

- Viewed horizontally rather than vertically, middleware is also in the middle of interactions between different application programs (possibly even running on different computer systems), because it provides mechanisms to support controlled interaction through coordination, persistent storage, naming, and communication.

- Relational database systems is one example of middleware.
  - ▶ Such systems provide a more sophisticated form of persistent storage than the files supported by most operating systems.

- File formats
  - ▶
  - ▶
- ▶

Data-driven Research

- Data-driven research is the science of letting data tell us what we are looking for.

- Database management is the science of efficiently storing and retrieving data.

- Data mining is the science of discovering hidden correlations in data.

Challenges for Data-driven Research

- In HPC, the concerns of storage and computing are traditionally separated and optimised independently from each other and the needs of the end-to-end user.

- Workflows composed of data, computing, and communication-intensive tasks should drive interfaces and hardware configurations to best support the programming models.

- Many processes still require experts. For example, porting a workflow from one system to another still requires adjusting runtime parameters of applications and deciding on how data is managed.

- Data-driven workflows may benefit from the explicit and simultaneous use of a locally heterogeneous set of computing and storage technologies.

I/O Performance

- There are several aspects involved in delivering high I/O performance to parallel applications, from hardware characteristics to methods that manipulate workloads to improve achievable performance.

- Running the same application with different I/O configurations gives the possibility to tune the I/O system according to the application access pattern.

- One way to predict application performance in HPC systems with different I/O configurations is by using modelling and simulation techniques.

I/O Path

The I/O path describes all the layers (and components) involved in I/O and how they interact. In brief, the I/O path of a write operation can be described as follows:

- When an application issues an I/O call, data is copied between the user-space buffer and the page cache that is offered in kernel-space.
- In kernel-space memory the data is cached and write operations can be deferred as long as free memory is available.
- At this point the write call can complete, because a programmer cannot modify kernel-space directly.
- A scheduler inside the kernel decides when modified pages are transferred to the block device.
- The mapping from offsets in logical files to addresses on the block storage is managed by a file system. Further, file systems provide the hierarchical namespace and offer additional management features.

## Characterizing Application I/O

How are applications using the I/O system, and how successful are they at attaining high performance?

- The best way to answer these questions is by observing behavior at the application and library level
- What did the application intend to do, and how much time did it take to do it?
- In this portion of the training course we will focus on **Darshan**, a scalable tool for characterizing application I/O activity.

Storage Stack Overview

Typical I/O Performance Issues

Access patterns:

- Access granularity

- Randomness

- Concurrency

- Load balance

- Access type

- Predictability

Typical I/O Performance Issues

I/O strategy:

- Caching algorithm

- Replication

- High availability (HA) support

- I/O forwarding

- Aggregation

- Scheduling

Typical I/O Performance Issues

Parallel file system:

- Design

- Implementation

- Resource consumption

- Communication

- Data distribution

- Metadata handling

- Consistency semantics

- Locking strategy

Challenges in Application I/O

- Leveraging aggregate communication and I/O bandwidth of clients
  - …but not overwhelming a resource limited I/O system with uncoordinated accesses!
- Limiting number of files that must be managed
  - Also a performance issue
- Avoiding unnecessary post-processing
- Often application teams spend so much time on this that they never get any further:
  - Interacting with storage through convenient abstractions
  - Storing in portable formats

Assess and Optimize the Application I/O Performance

- Develop general considerations about what influences the I/O performance
  - What?

- Analyze access pattern and define how it defines the performance of the I/O subsystems
  - How?

- Apply I/O strategies to improve the access pattern
  - Which?

- Identify options for the deployed optimization strategies in a specific parallel file system
  - Which?

I/O Performance Tuning "Rules of thumb"

- Use collectives when possible
- Use high-level libraries (e.g. HDF5 or PnetCDF) when possible
- A few large I/O operations are better than many small I/O operations
- Avoid unnecessary metadata operations, especially *stat()*
- Avoid writing to shared files with POSIX
- Avoid leaving gaps/holes in files to be written later

I/O Performance Models – Examples??

- Architectures and Storage Networks (SIMCAN) [1] is aimed at optimization of communications and I/O algorithms.
- Parallel I/O Simulator of Hierarchical Data (PIOsimHD) [2] was developed to analyze Message Passing Interface-Input/Output (MPI-I/O) performance and cluster hardware configurations.
- Co-design of Exascale Storage System (CODES) [3] is a framework for evaluating exascale storage system design points.
- High-Performance Simulator for Hybrid Parallel I/O and Storage Systems (HPIS3) [4] models the application workloads, parallel file system and storage system of the HPC environment.
- ABMS is an approach to modelling complex systems composed of autonomous agents.
NetCDF

- In a simple view, NetCDF is:
  - A data mode.
  - A file format.
  - A set of APIs and libraries for various programming languages.

- Together, the data model, file format, and APIs support the creation, access, and sharing of scientific data.

- NetCDF allows the user to describe multidimensional data and include metadata which further characterizes the data.

- NetCDF APIs are available for most programming languages used in geosciences.

Common Data form Language (CDL)

- The notation used to describe a NetCDF object is called CDL (network Common Data form Language), which provides a convenient way of describing NetCDF datasets.

- The NetCDF system includes utilities for producing human-oriented CDL text files from binary NetCDF datasets and vice-versa.
  - ▶ Example.

The Classic NetCDF Model

■ A NetCDF file (dataset) has a path name and possibly some dimensions, variables, global (file-level) attributes, and data values associated with the variables.

dimensions   variables   global attributes

The Classic NetCDF Model Characteristics

- A NetCDF file has named variables, attributes, and dimensions

- Variables are for data, attributes are for metadata (data about data)

- Dimensions are for specifying shapes of variables

- Attributes may apply to a whole file or to a single variable

- Variables may share dimensions, indicating a common grid

- One dimension may be of unlimited length

- Each variable or attribute has one of six types: char, byte, short, int, float, double

# The Classic NetCDF Model Limitations

- No real data structures, just multidimensional arrays and lists

- No nested structures, variable-length types, or ragged arrays

- Only one shared unlimited dimension for appending new data

- A flat name space for dimensions and variables

- Character arrays rather than "real" strings

- A small set of numeric types

The Classic NetCDF Format Limitations

- Large variables must be less than 4 GB (per record)

- No real compression supported, just scale/offset packing

- Changing a file schema (the logical structure of the file) may be very inefficient

- I/O is serial in Unidata NetCDF-3 (but see Argonne/Northwestern Parallel NetCDF project)

- Efficient access requires data for a variable to be written and read contiguously

NetCDF Data Models

- Classic: Simplest model – dimensions, variables, attributes
- Enhanced: More powerful model – adds groups, types, nesting
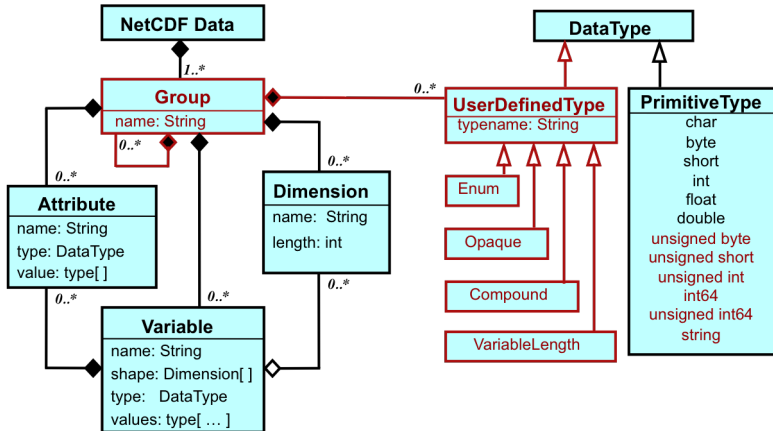

The NetCDF-4 Enhanced Data Model

- The new data model, which is known as the "Common Data Model" is part of an effort here at Unidata to find a common engineering language for the development of scientific data solutions.

- It contains the variables, dimensions, and attributes of the classic data model, but adds:
  - Groups – A way of hierarchically organizing data, similar to directories in a Unix file system.
  - User-defined types – The user can now define compound types (like C structures), enumeration types, variable length arrays, and opaque types.

The NetCDF-4 Enhanced Data Model

- A file has a top-level unnamed group.

- Each group may contain one or more named subgroups, user-defined types, variables, dimensions, and attributes.

- Variables also have attributes.

- Variables may share dimensions, indicating a common grid.

- One or more dimensions may be of unlimited length.

NetCDF-4 and HDF5

NetCDF-4 uses HDF5 as a storage layer:

- Provide performance advantages of HDF5
- Compression
- Chunking
- Efficient schema changes
- Useful for very large or complex data
- Suitable for high-performance computing

NetCDF Data Model

How is data stored in NetCDF?

```
NetCDF mynetcdf {
dimensions:
X=4;
Y=4;
Time=UNLIMITED;
variables:
float X(X);
float(Y);
int Time(Time);
float Temperature(time,X,Y);
data:
X=10,20,30,40;
Y=110,120,130,140;
Time=31,59,90;

Temperature=
```

ESDM Data Model
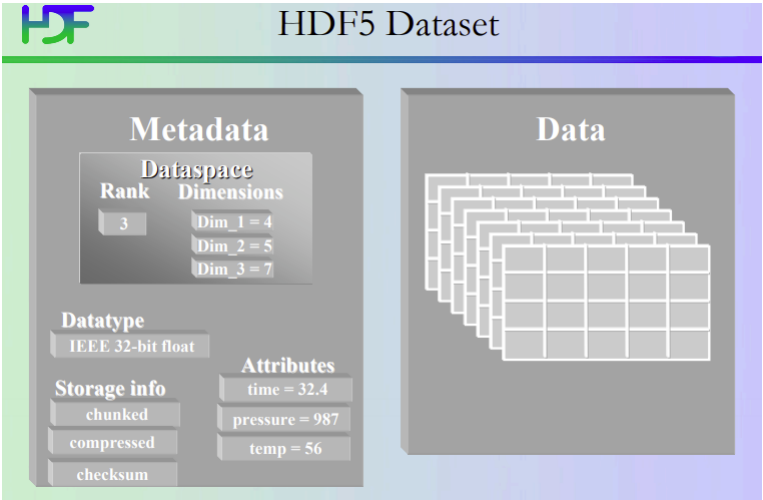

Experience-based "Best Practices" for Writing NetCDF Files

- **Conventions**
  - ▶ Developers should be familiar with and use existing NetCDF conventions, when practical.

- **Coordinate Systems**
  - ▶ Spatial and temporal location of data are supported by use of coordinate systems.

- **Variable Grouping**
  - ▶ How you group data into variables can determine whether common analysis and visualization software can effectively use the data.

- **Variable Attributes**
  - ▶ Conventional variable attributes supply necessary metadata.

Experience-based "Best Practices" for Writing NetCDF Files

- **Strings and Character Variables**
  - ▶ Use character data properly for representing text strings.

- **Calendar Date and Time**
  - ▶ Represent calendar dates and times with standards and conventions.

- **Packed Data Values**
  - ▶ Conventions for packing numeric data to save space have some subtleties.

- **Missing Data Values**
  - ▶ To indicate that data values are missing, invalid, or not written, special values are conventionally used.

Climate and Forecast (CF) Conventions

- The Climate and Forecast (CF) conventions are metadata conventions for earth science data, intended to promote the processing and sharing of files created with the NetCDF API.

- The CF conventions define metadata that are included in the same file as the data (thus making the file "self-describing").

- The purpose of the CF conventions is to require conforming datasets to contain sufficient metadata that they are self-describing in the sense that each variable in the file has an associated description of what it represents, including physical units if appropriate, and that each value can be located in space (relative to earth-based coordinates) and time.

- The CF conventions enable users of data from different sources to decide which data are comparable and allows building applications with powerful extraction, regridding, and display capabilities.

Create programs in C and Python that read and write NetCDF files in a metadata-aware manner
